

Features

- 2 channel analog input Class D audio amplifier in a small 7x7mm package
- Very low R_{DS(ON)} at 24.4 mΩ typical, enabling heatsink-less operation at 2x100W at 4Ω
- 95% efficiency Class D at 4Ω
- Split or single power supply capable
- Differential or single-ended input
- Multiple configuration options: 2xSE, BTL, PSE
- Over-current, over-temperature and under-voltage protections with self-reset feature
- Start/stop click noise reduction
- Clip and Fault reporting outputs

Applications

- Multi-channel home theatre system
- Studio monitor
- Active speaker
- Soundbar subwoofer
- Marine amplifier
- Aftermarket car audio system
- General-purpose audio power amplifier

Product validation

Qualified for standard applications according to the relevant tests of J-STD-020 and JESD22.

Description

The MA5332MS offers the same or higher output power than monolithic alternatives without heatsink and 50% less footprint. This MCM (multi-chip module) solution integrates 2 channel PWM controller, high voltage gate driver, and 4 low $R_{DS(ON)}$ MOSFETs. Like its predecessor, IR43x2M, It includes standard Class D protection features for reliable operation over various environmental conditions. As a powerful upgrade to IR43x2M and other monolithic solutions, MA5332MS' 7x7 mm PG- IQFN-42 package showcases the benefit of small footprint, high power density, and heatsink-less operation.

* In a typical application

4 Specifications

4.1 Absolute maximum ratings

Absolute Maximum Ratings indicate sustained limits beyond which damage to the device may occur. All voltage parameters are absolute voltages referenced to COM=VN1=VN2; all currents are defined positive into any lead. The Thermal Resistance and Power Dissipation ratings are measured under board mounted and still air conditions.

Table of contents

Note:

- *1. IN- and IN+ contain clamping diodes between the two pins.*
- *2. VAA -VSS, Vcc-COM and VBn-VSn contain internal shunt zener diodes. Note that the voltage ratings of these can be limited by the clamping current.*
- *3. For the rising and falling edges of step signal of 10V. Vss=15V to 100V.*
- *4. Per MOSFET.*
- *5. Repetitive rating, pulse width limited by maximum junction temperature.*

4.2 Recommended operating conditions

For proper operation, the device should be used within the recommended conditions below. The Vss and Vsn offset ratings are tested with supplies biased at COM=VN1=VN2, V_{AA} -V_{SS}=9.6V, V_{CC}=12V and V_{Bn}-V_{Sn}=12V. All voltage parameters are absolute voltages referenced to COM; all currents are defined positive into any lead.

Note:

6. Logic operational for Vs equal to –5V to +100V. Logic state held for Vs equal to –5V to –VBS.

7. GND input voltage is limited by IAAZ and ISSZ.

4.3 Electrical characteristics

Unless otherwise specified, the following apply:

- \bullet V_{CC} , V_{BS} = 12 V
- $V_{SS} = V_{S1} = V_{S2} = V_{N1} = V_{N2} = COM = OV$
- \bullet V_{AA}=9.6V
- \bullet T_A=25°C

7 Typical Implementation

The MA5332MS can be designed as single-ended BTL or PSE output, using a single or split power supply. Here are examples of typical configurations.

A configuration for single-ended input with split power supply sets the base example. The front end section refers to GND which is common to speaker output GND.

Figure 23 Inverting amplifier with Split Power Supply

Figure 24 Differential amplifier with Split Power Supply

Table of contents

The single-supply configuration uses a virtual GND which sits in the middle of the power supply rail. The frontend section of the amplifier refers to the virtual GND as a reference. This method uses differential input to receive an input signal from a different voltage potential. It is recommended to allow input capacitors to fully settle to steady-state values before releasing the CSD pin to start PWM oscillation. The load current and inductor ripple current flow through the bus splitting capacitor.

Figure 25 Typical Application Circuit with Single Power Supply

Balanced Tied Load (BTL) output takes two output legs for speaker output. It doubles output power with double load impedance. Any load current does not flow through supply dividing capacitor; therefore BTL configuration is free from GND fluctuations. Also, the bus splitting capacitor can be much smaller. Higher output power and absence of GND fluctuation make BTL suitable for subwoofer applications.

Figure 26 Typical Bridged Tied Load (BTL) Output Application with Split Power Supply

Table of contents

Figure 27 Typical Bridged Tied Load (BTL) Output Application with Single Power Supply

Parallel Single Ended (PSE) output parallels two channels' output legs for one speaker output. It doubles output current and makes it easier to drive a low impedance load. Higher output current with lower bus voltage makes PSE suitable for subwoofer applications.

9 PWM Modulator Design

The open-access front-end configuration of MA5332MS enables many ways to implement a PWM modulator. This section explains how PWM modulation works based on an example of a self-oscillating PWM modulator in a typical application.

Figure 30 MA5332MS Typical Control Loop Design

9.1 Input Section

The audio input stage of MA5332MS forms an inverting error amplifier. The voltage gain of the amplifier, G_{V} , is determined by the ratio between input resistor R_{IN} and feedback resistor R_{FB} .

$$
G_V = \frac{R_{FB}}{R_{IN}}
$$

Since the feedback resistor R_{FB} is part of an integrator time constant, which determines switching frequency, changing the overall voltage gain by R_{IN} is simpler and therefore recommended. Note that the input impedance of the amplifier is equal to the input resistor R_{IN} .

A DC blocking capacitor C3 should be connected in series with R_{IN} to minimize the DC offset voltage on the output. Due to potential distortion, a ceramic capacitor is not recommended. Minimizing the DC offset is essential to minimize the audible noise during power-ON and -OFF.

The connection of the non-inverting input IN+ is a reference for the error amplifier, and thus is crucial for audio performance. Connect IN+ to the signal reference ground in the system, which has the same potential as the negative terminal of the speaker output.

9.2 Control Loop Design

The MA5332MS allows the user to choose from numerous methods of PWM modulator implementations. In this section, all the explanations are based on a typical application circuit of a self-oscillating

9.3 PWM Frequency

Choosing the switching frequency entails making a trade-off between many aspects. At lower switching frequency, conduction losses in the MOSFET stage increases due to higher inductor ripple current. The output carrier leakage in the speaker output increases. At higher switching frequency, the efficiency degrades due to higher switching losses. Higher switching frequency supports wider audio bandwidth. The inductor ripple decreases yet core loss might increase. For these reasons, 400kHz is chosen for a typical design example.

Self-oscillating frequency has little influence from the bus voltage and input resistance RIN. Note that the nature of a self-oscillating PWM is for the switching frequency to decrease as PWM modulation deviates from idling.

Table 6 summarizes suggested values of components for a given target self-oscillating frequency. The front-end operational transconductance amplifier (OTA) output has limited voltage and current compliances. This set of component values ensures that OTA operates within its linear region for optimal THD+N performance. In case the target frequency is somewhere in between the frequencies listed in Table 6, simply adjust the frequency by tweaking R1.

Table 10 External Component Values vs. Self-Oscillation Frequency

Table of contents

9.4 Clock Synchronization

In the PWM control loop design example, the self-oscillating frequency can be set and synchronized to an external clock. Through a set of resistors and a capacitor, the external clock injects periodic pulsating charges into the integrator, forcing oscillation to lock up to the external clock frequency. A typical setup with 5 Vp-p 50% duty clock signal uses R_{CK}=22 kΩ and C_{CK}=100 pF in Figure 31. To maximize audio performance, the self-running frequency without clock injection should be 20 to 30% higher than the external clock frequency.

Figure 31 External Clock Synchronization

Figure 32 shows how a self-oscillating frequency locks up to an external clock frequency. A design of a 400 kHz self-oscillating frequency synchronizes to an external clock whose frequency is within the red border lines.

Table of contents

9.5 Click Noise Elimination

The MA5332MS has a unique feature that minimizes power-ON and -OFF audible click noise. When CSD is in between Vth1 and Vth2 during start-up, an internal closed loop around the OTA enables an oscillation that generates voltages at COMP and IN-, bringing them to steady-state values. It runs at around 1 MHz, independent from the switching oscillation.

Figure 33 Audible Click Noise Elimination

As a result, all capacitive components connected to COMP and IN- pins, such as C1, C2, C3 and Cc in Figure 33, are pre-charged to their steady-state values during the start-up sequence. This allows instant settling of closedloop PWM operation.

To utilize the click noise reduction function, the following conditions must be met.

- 1. CSD pin has slow enough ramp up from Vth1 to Vth2 such that the voltages in the capacitors can settle to their target values.
- 2. High-side bootstrap power supply needs to be charged up prior to starting oscillation.
- 3. Audio input has to be zero.
- 4. For internal local loop to override external feedback during the startup period, DC offset at speaker output prior to shutdown release has to satisfy the following condition.

Table of contents

9.6 Differential Input

Figure 34 shows an example of a differential input configuration. This design is useful in a single supply configuration. Use $R_{IN1}=R_{IN2}$, $R_{FB1}=R_{FB2}$, C3=C4.

Voltage gain is given by a ratio between R_{IN} and R_{FB} .

$$
G_V = \frac{R_{FB}}{R_{IN}}
$$

Figure 34 Differential Input

Although component values in the feedback network are balanced between inverting and non-inverting inputs, the integration capacitor path in the non-inverting input creates unbalance at high frequencies, causing slightly higher distortion compared to an unbalanced input configuration. To improve the THD degradations, place optional RC network R2=R1 and C5=C1.

10 Operational Mode

The CSD pin determines the operational mode of the MA5332MS as shown in Figure 35. The OTA has three operational modes: shutdown, pop-less startup and normal operation; while the gate driver section has two modes: shutdown and normal operation.

When V_{CSD} < Vth2, the IC is in shutdown mode and the input OTA is cut off. When Vth2< V_{CSD} < Vth1, the output MOSFETs are still in shutdown mode. The OTA is activated and starts local oscillation for pop-less start-up which pre-biases all the capacitive components in the error amplifier. When V_{CSD} >Vth1, the MA5332MS enters normal operation mode and PWM operation starts.

Figure 35 V_{CSD} and Operational Mode

10.1 Self-oscillation Start-up Condition

The MA5332MS requires the following conditions in order for pop-less startup to work properly.

- All the control power supplies, VAA, VSS, VCC and VBS are above the under-voltage lockout thresholds.
- CSD pin voltage is over Vth1 threshold.
- $|i_{IN}| < |i_{FB}|$

Where
$$
i_{IN} = \frac{V_{IN}}{R_{IN}}
$$
, $i_{FB} = \frac{V_{+B}}{R_{FB}}$.

The duration CSD voltage transitioning from Vth2 to Vth1 is long enough to pre-charge input and integration capacitors around OTA section.

11 Protections

Figure 36 Protection Functional Block Diagram (MA5332MS)

The internal protection control block dictates the operational modes, normal or shutdown, using the input of the CSD pin. In shutdown mode, the controller IC turns off internal power MOSFETs.

The CSD pin provides five functions.

- 1. Power up delay timer
- 2. Self-reset timer
- 3. Shutdown input
- 4. Latched protection configuration
- 5. Shutdown status output (host I/F)

The CSD pin cannot be paralleled with another MA5332MS directly.

The operating statuses of the protection features are shown in Table 2.

Table 11 Events and Actions of CSD and FAULT

*CSD recycle: CSD pin voltage discharges down to Vth2 and charges back to VAA, if CSD pin is configured as self reset protection.

11.1.1 Self-Reset Protection

Attaching a capacitor between CSD and V_{ss} configures the MA5332MS self-reset protection mode.

Upon an OCP event, the CSD pin discharges the external capacitor voltage V_{CSD} down to the lower threshold V_{th2} to reset the internal shutdown latch. Then, the CSD pin begins to charge the external capacitor, Ct, in an attempt to resume operation. Once the voltage of the CSD pin rises above the upper threshold, V_{th1} , the IC resumes normal operation.

Figure 37 Self-Reset Protection Configuration

11.1.2 Designing Ct

The external timing capacitor, Ct, programs self-reset timings: t_{REST} and t_{SU} .

- t_{RESET} is the time that elapses from when the IC enters the shutdown mode to the time when the IC resumes operation. t_{RESET} should be long enough to avoid over heating the MOSFETs from the repetitive sequence of shutting down and resuming operation during over-current conditions. In most applications, the minimum recommended time for t_{REST} is 0.1 seconds.
- t_{SU} is the time between powering up the IC in shutdown mode to the moment the IC releases shutdown to begin normal operation.

The Ct determines t_{RESET} and t_{SU} as following equations:

Table of contents

$$
t_{RESET} = \frac{Ct \cdot V_{AA}}{1.1 \cdot I_{CSD}} \quad \text{[s]}
$$

$$
t_{SU} = \frac{Ct \cdot V_{AA}}{0.7 \cdot I_{CSD}} \quad [s]
$$

where I_{csp}: the charge/discharge current at the CSD pin V_{AA} : the floating input supply voltage with respect to V_{SS} .

11.1.3 Shutdown Input

During normal operation, pulling the CSD pin below the upper threshold Vth1 forces the IC into shutdown mode. Figure 38 shows how to add an external discharging path to shutdown the PWM.

Figure 38 Shutdown Input

11.1.4 Latched Protection

Connecting CSD to VAA through a 10 kΩ or less resistor configures latched protection mode. The internal shutdown latch stays in shutdown mode after the overcurrent is detected. An external reset switch brings CSD below the lower threshold Vth2 for a minimum of 200 ns and resets the latch. At first power-up, a reset signal to the CSD pin is required to release the IC from shutdown mode.

Figure 39 Latched Protection with Reset Input

11.1.5 Interfacing with System Controller

The MA5332MS can communicate with an external system controller through a simple interfacing circuit shown in Figure 40. A generic PNP transistor, U1, detects the sink current at the CSD pin during protection event and outputs a shutdown flag signal to an external system controller. Another generic NPN transistor, U2, can then reset the internal protection logic by pulling the CSD voltage below the lower threshold Vth2. After the first power-up sequence, a reset signal to the CSD pin is required to release the IC from shutdown mode.

Figure 40 Interfacing CSD with System Controller

Protections

11.2 Over Current Protection (OCP)

The MA5332MS features over current protection to protect the internal power MOSFETs during abnormal load conditions. The control logic diagrams are in Figure 41. As soon as either the high-side or low-side current sensing block detects over current, the following sequence will occur.

- 1. The shutdown latch flips its logic states from normal operational mode to shutdown mode.
- 2. Low-side and high-side MOSFETs go into an off state condition.
- 3. The CSD pin starts discharging the external capacitor Ct.
- 4. When voltage across Ct falls below the lower threshold Vth2, COMP2 resets the shutdown latch to normal mode.
- 5. The CSD pin starts charging the external capacitor Ct.
- 6. When V_{CSD} goes above the upper threshold Vth1, the logic on COMP1 toggles and the IC resumes operation.

Figure 41 summarizes the above. As long as the over current condition exists, the IC will repeat the over current protection sequence at a repetitive rate set by the CSD capacitor.

Figure 41 Overcurrent Protection Timing Chart

Protections

11.3 Over Temperature Protection (OTP)

If the junction temperature T_J of the controller IC exceeds the on-chip thermal shutdown threshold, T_{SD}, the onchip over temperature protection shuts down the PWM.

11.4 Under Voltage Protection (UVP)

In order to prevent a partial on-state of the internal MOSFET, under-voltage protection monitors the low side and high side gate bias supplies, VCC and VB. When VCC is below UVLO, both high and low side MOSFETs are turned off. When the high side supply V_{BS} is below the UVLO threshold, the high side output is disabled, while the low side works normally.

12 Status Output

12.1 Fault Output

FAULT output is an open drain output referenced to GND to report whether the MA5332MS is in shutdown mode or in normal operating mode. If the FAULT pin is open, the MA5332MS is in normal operation mode, i.e. the output MOSFETs are active. The following conditions trigger shutdown internally and pulls the FAULT pin down to GND.

- Over Current Protection
- Over Temperature Protection
- Shutdown mode from CSD pin voltage

Figure 42 Fault Output

Status Output

12.2 CLIP Output

When the output of the amplifier loses track of an expected target value, the amplifier enters into clipping condition.

The CLIP detection block monitors the COMP pin voltage with a window comparator. The CLIP pin is pulled to GND when a clipping condition is detected. The detection thresholds in the COMP pin are at 10% and 90% of VAA-VSS. The CLIP outputs are disabled in shutdown mode.

Figure 43 CLIP Detection

Power Supply Design

13 Power Supply Design

13.1 Supplying VAA and VSS

VAA and VSS are supply voltages to the front-end of the analog section, hence are noise sensitive. For best audio performance, use regulated power supplies for VAA and VSS.

Figure 44 Supplying VAA and VSS with External Voltage Regulators

When switched-mode regulators are used as supply voltages for VAA and VSS, place a two-stage R-C noise filter in the supply lines as shown in Figure 45.

Figure 45 Supplying VAA and VSS from Switched Mode Power Supply

13.2 Supplying VCC and VB

Figure 46 shows the recommended power supply configuration for gate driver power supplies. The gate driver stage has three power supply inputs:

- 1. VCC-COM: low side gate drive supply
- 2. VB1-VS1: CH1 high side gate drive supply
- 3. VB2-VS2: CH2 high side gate drive supply

The low-side power supply, VCC, feeds the internal gate drive logic and low side gate driver. In order to protect VCC from switching noise generated by the VS node, it is recommended to insert a few ohms of R_{VBS} in the bootstrap charging path.

The high-side driver requires a floating supply VBn referenced to the respective switching node VSn where the source of the output MOSFET is connected. A charge pump method (floating bootstrap power supply) eliminates the need for a floating power supply and thus is used in the typical application circuit. The floating bootstrap power supply charges the bootstrap capacitor C_{BS} from the low-side power supply VCC during the low-side MOSFET ON period. When the high-side MOSFET is ON, the diode cuts off and floats the VBS supply. C_{BS} retains its VB supply voltage for the rest of the high-side ON duration.

Power Supply Design

$$
I_{VCC} \approx I_{QCC} + I_{QBS} + 2(Q_G \cdot f_{PWM})_{\text{/per channel}}
$$

Recommend to have minimum 20% design margin for Ivcc.

Figure 46 Recommended Power Supply Configurations for Output Stage

13.2.1 Choosing Bootstrap Capacitance

Often MA5332MS uses hard clipping condition. The continuous high-side ON duration could continue as long as half of the lowest audio frequency, tens of miliseconds. A typical application uses a 22 uF C_{BS} to support low audio frequency clipping. A ceramic capacitor (X7R, X5R or X5S type) or aluminium electrolytic capacitor with 25 V or higher voltage rating is recommended.

13.2.2 Choosing Bootstrap Diode

Use a bootstrap charging diode with voltage rating of 1.5 x the maximum bus voltage. In order to charge the bootstrap capacitor in a very short low-side ON period with a high PWM modulation ratio, a fast recovery diode type (trr<50ns) is recommended.

13.2.3 Charging VBS Prior to Start

For proper start-up, pre-charging the bootstrap supply V $_{BS}$ prior to PWM start-up is necessary for self-oscillating PWM modulator topologies. A charging resistor, R_{CHARGE} , inserted between the positive supply bus and V_{B} , charges C_{BS} prior to switching start as shown in Figure 47. The minimum resistance of R_{CHARGE} is limited by the maximum PWM modulation index of the system. When the high-side MOSFET is on, R_{CHARGE} drains the bootstrap power supply together with the quiescent current, I_{QBS} so it reduces the holding time, resulting in maximum continuous high-side on time.

The maximum resistance of R_{CHARGE} is limited by the current charge capability of the resistor during startup.

Power Supply Design

Pre-charging current flows into the speaker load. In order to startup without the load connected, a dummy load R_{dummy} in parallel with the speaker output provides a pre-charging current path.

Figure 47 Bootstrap Supply Pre-Charging

Power Supply Design

13.3 Power Supply Sequence

The protection control block in the MA5332MS monitors the status of V_{AA} and V_{CC} to ensure that both voltage supplies are above their respective UVLO (under voltage lockout) thresholds before starting normal operation. If either V_{AA} or V_{CC} is below the under voltage threshold, the output MOSFETs are disabled in shutdown mode until both V_{AA} and V_{cc} rise above their voltage thresholds. As soon as V_{AA} or V_{cc} falls below its UVLO threshold, protection logic in the MA5332MS turns off high-side and low-side.

The data contained in this document is exclusively intended for technically trained staff. It is the responsibility of customer's technical departments to evaluate the suitability of the product for the intended application and the completeness of the product information given in this document with respect to such application.

For further information on the product, technology, delivery terms and conditions and prices please contact your nearest Infineon Technologies office (**www.infineon.com**).

WARNINGS

Due to technical requirements products may contain dangerous substances. For information on the types in question please contact your nearest Infineon Technologies office.

Except as otherwise explicitly approved by Infineon Technologies in a written document signed by authorized representatives of Infineon Technologies, Infineon Technologies' products may not be used in any applications where a failure of the product or any consequences of the use thereof can reasonably be expected to result in personal injury.
