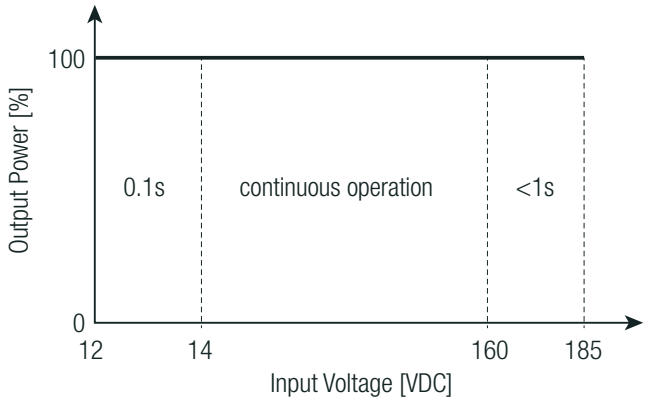
Input Voltage Range



Continuous full power operation is rated between 14V and 160V, including full load start-up.
Once running, the converter will operate for short periods of time over an extended input voltage range down to 12V and up to 185V, thus covering all EN50155 under-voltage and over-voltage transient conditions.

OUTPUT VOLTAGE TRIMMING

It allows the user to increase or decrease the output voltage of the module. This is accomplished by connecting an external resistor between the Trim pin and either the +Sense or -Sense pins. With an external resistor between the Trim and +Sense pin, the output voltage increases. With an external resistor between the Trim and -Sense pin, the output voltage decreases. The external Trim resistor needs to be at least 1/8W of rated. The values for trim resistors shown in trim tables below are according to standard E96 values; therefore, the specified voltage may slightly vary.

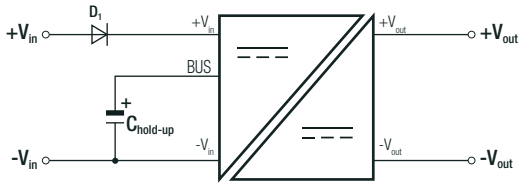
HOLD UP TIME SETTING

An additional BUS pin (version with suffix -B) supplies a fixed voltage for capacitor charging. Meeting S2, S3, and C2 conditions as described in EN50155 requires numerous aluminum electrolytic capacitors for ample energy. High voltage capacitors occupy significant space, posing challenges for limited specifications. To address varying system voltages, different capacitance values and withstand-voltage capacitors are needed.

The enhanced hold-up function resolves this by using the same capacitors for various system voltages and interruptions. This innovation is ideal for railway system power boards. Unlike conventional hold-up capacitors, the BUS pin consistently provides 21.4V, compatible with 25V rated capacitors for both 24V and 110V systems, ensuring a uniform solution in terms of capacitance value and quantity.

By connecting capacitors to the BUS pin, the inrush current is restricted effectively via the internal charging path that could reduce the extra external components of the whole system.



The formula provided below allows for the calculation of capacitor capacitance, with the potential for adjusting the margin based on practical application requirements.

$$C_{hold\text{-}up} = 0.0096 \times P_{IN} \times t$$

P_{IN}	= Input Power	[W]
t	= interruption duration	[s]
$C_{hold\text{-}up}$	= calculated capacitor	[µF]

Practical Example:

P_{OUT} = 60W
P_{IN} = 67.4W
V_{IN} = 110VDC
t = 0.01s

$C_{hold\text{-}up} = 0.0096 \times 67.4 \times 0.01 = 0.0064704$ F

$C_{hold\text{-}up}$ **according to E96** ≈ 6490µF
