EVALUATION KIT AVAILABLE Rail-to-Rail, 200kHz Op Amp with Shutdown in a Tiny, 6-Bump WLP

General Description

The MAX44265 op amp features a maximized ratio of gain bandwidth (GBW) to supply current and is ideal for battery-powered applications such as handsets, tablets, notebooks, and portable medical equipment. This CMOS op amp features an ultra-low input-bias current of 1pA, rail-to- rail input and output, low supply current of 4 μ A, and operates from a single 1.8V to 5.5V supply. For additional power conservation, the IC also features a low-power shutdown mode that reduces supply current to 1nA and puts the amplifier's outputs in a high-impedance state. This device is unity-gain stable with a 200kHz GBW product.

It is available in a space-saving, 0.9mm x 1.3mm, 6-bump WLP package and is specified over the -40°C to +85°C extended operating temperature range.

Applications

Cell Phones Tablet/Notebook Computers Mobile Accessories Battery-Powered Devices

- 200kHz GBW
- Ultra-Low 4µA Supply Current
- Single 1.8V to 5.5V Supply Voltage Range
- Ultra-Low 1pA Input Bias Current
- ♦ Rail-to-Rail Input and Output Voltage Ranges
- ◆ Low ±200µV Input Offset Voltage
- ♦ Low 0.001µA Shutdown Current
- High-Impedance Output During Shutdown
- Unity-Gain Stable
- Available in a Tiny, 0.9mm x 1.3mm, 6-Bump WLP Package

ABSOLUTE MAXIMUM RATINGS

Operating Temperature Range	40°C to +85°C
Junction Temperature	+150°C
Storage Temperature Range	65°C to +150°C
Soldering Temperature (reflow)	+260°C

Stresses beyond those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. These are stress ratings only, and functional operation of the device at these or any other conditions beyond those indicated in the operational sections of the specifications is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

MAX44265

_Pin Configuration

_Pin Description

PIN	NAME	FUNCTION			
A1	IN+	Noninverting Amplifier Input			
A2	V _{SS}	Negative Supply Voltage			
B1	IN-	Inverting Amplifier Input			
C1	OUT	Amplifier Output			
B2	V _{DD}	Positive Supply Voltage			
C2	SHDN	Shutdown			

Detailed Description

Featuring a maximized ratio of GBW to supply current, low operating supply voltage, low input bias current, and rail-to-rail inputs and outputs, the MAX44265 is an excellent choice for precision or general-purpose, lowcurrent, low-voltage, battery-powered applications. This CMOS device consumes an ultra-low 4 μ A (typ) supply current and has a 200 μ V (typ) offset voltage. For additional power conservation, the IC features a low-power shutdown mode that reduces supply current to 1nA (typ) and puts the amplifier's output in a high-impedance state. This device is unity-gain stable with a 200kHz GBW product, driving capacitive loads up to 30pF. The capacitive load can be increased to 250pF when the amplifier is configured for a 10V/V gain.

Rail-to-Rail Inputs and Outputs

The IC has a parallel-connected n- and p-channel differential input stage that allows an input common-mode voltage range that extends 100mV beyond the positive and negative supply rails, with excellent common-mode rejection. The IC is capable of driving the output to within 5mV of both supply rails with a 100k Ω load. This device can drive a 5k Ω load with swings to within 60mV of the rails. Figure 1 shows the output voltage swing of the IC configured as a unity-gain buffer powered from a single 3V supply.

Low Input Bias Current

The IC features ultra-low 1pA (typ) input bias current. The variation in the input bias current is minimal with changes in the input voltage due to very high input impedance (in the order of $1G\Omega$).

Applications Information

Driving Capacitive Loads

The IC's amplifier is unity-gain stable for loads up to 30pF. However, the capacitive load can be increased to 250pF when the amplifier is configured for a minimum gain of 10V/V. Applications that require greater capacitive-drive capability should use an isolation resistor between the output and the capacitive load (Figure 2). Also, in unity-gain applications with relatively small R_L (approximately $5k\Omega$), the capacitive load can be increased up to 200pF.

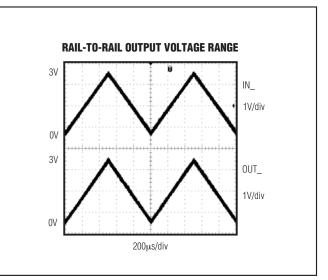

Figure 1. Rail-to-Rail Output Voltage Range

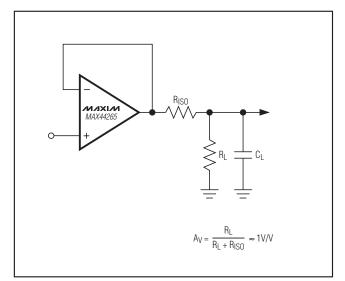

Figure 2. Using a Resistor to Isolate a Capacitive Load from the Op Amp

Power-Supply Considerations

The IC is optimized for single 1.8V to 5.5V supply operation. A high amplifier power-supply rejection ratio of 95dB (typ) allows the devices to be powered directly from a battery, simplifying design and extending battery life.

Power-Up Settling Time

The IC typically requires 5µs after power-up. Supply settling time depends on the supply voltage, the value of the bypass capacitor, the output impedance of the incoming supply, and any lead resistance or inductance between components. Op-amp settling time depends primarily on the output voltage and is slewrate limited. Figure 3 shows MAX44265 in a noninverting voltage follower configuration with the input held at midsupply. The output settles in approximately 18µs for $V_{DD} = 3V$ (see the *Typical Operating Characteristics* for power-up settling time).

Shutdown Mode

The IC features an active-low shutdown input. The device enters shutdown in $2\mu s$ (typ) and exit in $30\mu s$ (typ). The amplifier's outputs are in a high-impedance state in shutdown mode. Drive SHDN low to enter shutdown. Drive SHDN high to enable the amplifier.

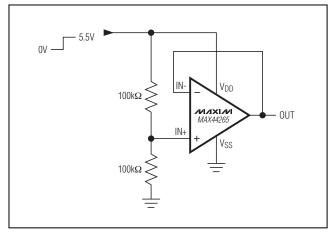

Figure 3. Power-Up Test Configuration

Power-Supply Bypassing and Layout

To minimize noise, bypass V_{DD} with a 0.1 μF capacitor to ground, as close to the pin as possible.

Good layout techniques optimize performance by decreasing the amount of stray capacitance and inductance to the op amps' inputs and outputs. Minimize stray capacitance and inductance by placing external components close to the IC.
